

A point of inflection is a point where a curve crosses its own tangent, for example  $f(x) = x^3$  graph has a point of inflection at origin  $(0,0)$

A point of inflection has property that  $y''(x)$  changes sign. ~~at~~

$$f(x) = x^3, \quad f'(x) = 3x^2$$

$f''(x) = 6x$  changes sign at  $x = 0$ .

A sufficient condition for  $a$  to be a point of inflection is

$$f''(a) = 0 \quad \text{and} \quad f'''(a) \neq 0$$

Example  $f(x) = x^4 - 2x^2$

$$f'(x) = 4x^3 - 4x = 4x(x^2 - 1)$$

stationary points at  $x=0, x=\pm 1$

$$f''(x) = 12x^2 - 4$$

$$f''(0) = -4 \quad x=0 \text{ is a local maximum}$$

$$f''(\pm 1) = 8 \quad x=\pm 1 \text{ local minima}$$

$$f''(x) = 0 \quad \text{if} \quad x^2 = \frac{1}{3} \quad \text{or} \quad x = \pm \frac{1}{\sqrt{3}}$$

$$f'''(x) = 24x \neq 0 \quad \text{if} \quad x = \pm \frac{1}{\sqrt{3}}$$

$x = \pm \frac{1}{\sqrt{3}}$  points of inflection

## Curve Sketching

No general way to sketch a graph - sometimes free hand ~~sketch~~ sketch impossible. The following can be useful:

(i) Any special features, eg odd, even or periodic?

(ii) Intercepts - points where graph intersects  $x$  or  $y$  axes

(iii) Stationary points or points of inflection

(iv) linear asymptotes

graph approaches a line as  $x \rightarrow \infty$  or  $x \rightarrow -\infty$

or a vertical line as  $x \rightarrow a$  (a finite)

## Linear Asymptotes

Rational functions can have linear asymptotes

$$(i) f(x) = \frac{x^3}{1-x^2} \quad \text{odd}$$

graph has vertical asymptotes at  $x = \pm 1$ . For large  $x$  (positive or negative)

$$f(x) \approx -x$$

$$f(x) = \frac{x}{\frac{1}{x^2} - 1} = -x \left(1 - \frac{1}{x^2}\right)^{-1}$$

$$= -x \left(1 + \frac{1}{x^2} + \frac{1}{x^4} + \dots\right)$$

$$= -x - \frac{1}{x} - \frac{1}{x^3}$$

For small  $x$   $f(x) \approx x^3$

$$\begin{aligned}
 f(x) &= x^3(1-x^2)^{-1} \\
 &= x^3(1+x^2+x^4+\dots) \\
 &\approx x^3
 \end{aligned}$$

(ii) What are the linear asymptotes

of  $y = \log (\cosh x)$

## Polar Graphs

Have described graphs  
via functions, equations  
and parametrically. Another  
way is through polar  
coordinates

Can replace cartesian  
coordinates  $(x, y)$   
with polar coordinates  $(r, \theta)$

$r$  = distance from origin

$\theta$  = angle between positive  
 $x$  axis and line segment

$OP$ . Have  $x = r \cos \theta$   
 $y = r \sin \theta$

$\theta$  is periodic - replacing  $\theta$  with  $\theta + 2\pi$  has no effect.

Examples of polar curves:

(i)  $r = 1$

(ii)  $r = |\cos \theta|$

(iii)

$$r = \frac{L}{1 + e \cos \theta}$$

$L$  constant

$e \geq 0$   
constant

$e = \text{eccentricity}$

This gives a conic section!

Conic Section (in cartesian)

$$Ax^2 + By^2 + Cxy + Dx + Ey + F = 0$$

(A, B, C, D, E, F are  
constants) defines  
a conic section

Degenerate cases

nothing

a point

a line

two lines

Non-degenerate case

ellipse

parabola

hyperbola
